Plata-Salaman, Carlos R., Sergey E. Ilyin, and Dave Gayle. Brain cytokine mRNAs in anorectic rats bearing prostate adenocarcinoma tumor cells. Am. J. Physiol. 275 (Regulatory Integrative Comp. Physiol. 44): R566–R573, 1998.—Cancer is consistently associated with anorexia. The Lobund-Wistar rat model of prostate cancer exhibits clinical manifestations (including anorexia) that resemble many aspects of the human disease. Cytokines are proposed to be involved in cancer-associated anorexia. Here we investigated mRNA profiles of feeding-modulatory cytokines and neuropeptides in specific brain regions of anorectic Lobund-Wistar rats bearing prostate adenocarcinoma tumor cells. Interleukin (IL-1)β system components (ligand, signaling receptor, receptor accessory proteins, receptor antagonist), tumor necrosis factor-α, transforming growth factor-β1, glycoprotein 130 (IL-6 receptor signal transducer), proopiomelanocortin (POMC, opioid peptide precursor), and neuropeptide Y (NPY) mRNAs were analyzed with sensitive and specific RNase protection assays. The same brain region sample was assayed for all components. The data show that early anorexia in tumor-bearing rats was associated with an upregulation of IL-1β mRNA in the brain regions examined (cerebellum, cortex, and hypothalamus). IL-1 receptor antagonist (IL-1Ra) mRNA and IL-1 receptor type I mRNA levels were also significantly increased in the cortex and hypothalamus. All other cytokine components, POMC, or NPY mRNA levels were not significantly different between tumor-bearing and pair-fed (control) rats. IL-1β mRNA and IL-1Ra mRNA were also significantly upregulated in the spleen of tumor-bearing rats. These data suggest that 1) IL-1β mRNA upregulation in the brain may be relevant to the anorexia exhibited by the tumor-bearing Lobund-Wistar rat and 2) in vivo characterization of cytokine components in discrete brain regions during cancer is necessary to understand underlying molecular mechanisms responsible for cancer-associated neurological manifestations.

interleukin; tumor necrosis factor; growth factor; nervous system; neuroimmunology; hypothalamus; cortex; cerebellum; cancer; food intake; feeding; anorexia

PROSTATE ADENOCARCINOMA is the most common cancer in men (10). The Lobund-Wistar rat model of autochthonous prostate cancer exhibits clinical manifestations (including anorexia) that resemble many aspects of the human disease (24, 25). Lobund-Wistar rats can be inoculated with prostate adenocarcinoma tumor cells derived from prostate adenocarcinomas that develop spontaneously in aged pathogen-free Lobund-Wistar rats (25). The transplanted prostate adenocarcinoma cells produce a local subcutaneous tumor. These tumor cells are transplantable only to the Lobund-Wistar strain (26). Thus the Lobund-Wistar tumor-bearing rat model allows investigation of tumor-associated processes from initiation to promotion to progression stages.

Cancer progression is multifactorial and involves complex chemical cascades and cell-to-cell interactions. These can be mediated by chemical factors produced by the tumor and/or the host, including cytokines, which are proposed to play a role in various aspects of tumor biology. Constitutive production of cytokines and growth factors has been reported in prostate gland cancer (9, 10). Studies in humans and animals support the involvement of cytokines in the induction of clinical manifestations (including anorexia) during cancer (18). Several studies have reported increased circulating levels of cytokines in a number of patients with various types of cancer, including prostate adenocarcinoma, but not all types (14, 18, 32). Thus no conclusive evidence has been obtained on a requirement of increased cytokine concentrations in the circulation to demonstrate cytokine involvement in the induction of cancer-associated neurological manifestations (15, 18). Cytokines have a short half-life and act not only in an endocrine fashion but also via paracrine, autocrine, and intracrine manners, activities that cannot be detected in the circulation. In fact, paracrine interactions represent a predominant mode of cytokine action. This suggests that cytokines may be involved in cancer-related clinical manifestations due to local synthesis of cytokines in an organ, e.g., the brain. In the present study we tested this possibility.

Lobund-Wistar rats bearing prostate adenocarcinoma tumor cells were continuously monitored for the initiation and progression of anorexia. After a definitive establishment of early anorexia, the control (pair fed) and tumor-bearing rats were killed, and their brains and peripheral organs were dissected. Various cytokine and neuropeptide component mRNAs were determined in the brain (cerebellum, cerebral cortex, and hypothalamus) and periphery (spleen, liver, and tumor) using sensitive and specific RNase protection assays. We focused on the interleukin (IL-1)β system and tumor necrosis factor-α (TNF-α) because of their relevance as anorexigenic cytokines (18) and their proposed involvement in malignant processes (e.g., Refs. 4, 13, 18, and 31). The IL-1β system includes IL-1β [predominant released form of IL-1 (3)], IL-1 receptor type I (IL-1RI; responsible for IL-1β signaling (27), modulation of the in vivo acute phase response (16), and induction of neurological manifestations (12, 28)), IL-1 receptor accessory protein (IL-1R AcP; a protein that increases binding affinity of IL-1β for IL-1RI when the 2 proteins...
are coexpressed (5, 33); IL-1R AcP expression also correlates with IL-1 responsiveness (33), and IL-1 receptor antagonist [IL-1Ra; an endogenous inhibitor that antagonizes, by competitive inhibition, IL-1β-induced central nervous system actions (3, 17) and binds to IL-1RI with nearly the same affinity as that for IL-1β]. The simultaneous investigation of various components of a cytokine system (i.e., the ligand, signaling receptor, receptor accessory protein, and endogenous inhibitor) can provide information on the feedback regulation and contribution of each cytokine system component.

We also examined transforming growth factor-β1 (TGF-β1), which is proposed to stimulate tumor progression (6) and inhibit IL-1β and TNF-α activity (21). Messenger RNA levels of the following components were also assayed: glycoprotein 130 (gp130), a common component of a cytokine system (i.e., the ligand, signaling receptor, receptor accessory protein, and endogenous inhibitor) can provide information on the feedback regulation and contribution of each cytokine system component.

**Materials and Methods**

Subjects and maintenance. Male Lobund-Wistar rats (control and tumor bearing) were purchased from Dr. Morris Pollard (Lobund Laboratory, University of Notre Dame, Notre Dame, IN). The prostate gland adenocarcinoma tumor cells were inoculated subcutaneously into the outer side of the right leg of ~12-wk-old rats in Dr. Pollard's laboratory; control Lobund-Wistar rats received the subcutaneous administration of vehicle solution. Shortly afterward, the rats were received at the University of Delaware, placed individually, and maintained ad libitum on powdered rat food (Labdiet, PMI Feeds, St. Louis, MO) and tap water as previously described (23). The behavior of the rats and development of the tumor were monitored daily. Artificial light illumination was from 0600 to 1800, and room temperature was kept at 21 ± 2°C.

Powdered food consumption. The measurement of powdered food intake was the same as in previous studies (23). In all cases, food intake was measured to within 0.1 g. Rats were fed ad libitum daily, except between 1730 and 1800 when food was removed to be measured and replaced. Premeasured food was presented at 1800. Food intake was measured at 1730 (total daily consumption from 1800 to 1730).

Dissection of brain regions. After the monitoring period, rats were decapitated and their brains were quickly removed (~30 s from time of decapitation) and immediately placed in oxygenated PBS solution at 2–4°C. The brain was rinsed several times, and the cerebellum (vermis), parietofrontal cortex, and the complete hypothalamus were dissected with a tissue-slicer blade. Samples from peripheral organs (spleen and liver) and the tumor were also taken. In all cases, the same investigator performed the procedure. Each tissue sample was immediately homogenized with guanidine thiocyanate-phenol solution (see RNA isolation and analysis of IL-1β, IL-1Ra, IL-1RI, IL-1R AcP and II, TNF-α, TGF-β1, gp130, POMC, NPY, β-actin, and GAPDH mRNAs) and frozen at −85°C. The tissue samples were number coded for further processing and analyses. The complete dissection and homogenization took ~6 min.

**RNA isolation and analysis of IL-1β, IL-1Ra, IL-1RI, IL-1R AcP and II, TNF-α, TGF-β1, gp130, POMC, NPY, β-actin, and GAPDH mRNAs.** Total cell RNA was isolated from the tissue samples after homogenization of the samples in guanidine thiocyanate-phenol solution (Tris Reagent, Molecular Research Center, Cincinnati, OH) using a microtissue grinder. Each sample was homogenized and processed individually. RNA concentration was determined by spectrophotometry at an absorbance of 260 nm. RNA integrity was assessed by agarose gel electrophoresis with ethidium bromide staining. The levels of rat β-actin and rat glyceraldehyde-3-phosphate dehydrogenase (GAPDH) mRNAs were determined by RNase protection to confirm that an assay was consistent and that an equal amount of total cell RNA was used for each assay.

Riboprobes were prepared as previously described (7, 22). Probe synthesis was conducted with 1 mM each of CTP, ATP, and UTP, 9.38 µM of [32P]GTP (800 Ci/mmol), and 25 µM of unlabeled GTP. [32P]GTP that was not incorporated into the probe was removed by two ethanol precipitations in the presence of 2.5 M ammonium acetate. RNase protection assays were used to detect the IL-1β, IL-1RI, IL-1R AcPs, IL-1Ra, TNF-α, TGF-β1, gp130, POMC, NPY, β-actin, and GAPDH mRNAs.

Hybridization reactions containing 20.0 µg of total cell RNA and 2.5 × 10⁴ counts/min each of IL-1β, IL-1RI, IL-1R AcP, IL-1Ra, gp130, TGF-β1, and 1.5 × 10⁴ counts/min each of TNF-α and GAPDH antisense probe were used to detect the IL-1β, IL-1RI, IL-1R AcPs, IL-1Ra, TNF-α, TGF-β1, gp130, POMC, NPY, β-actin, and GAPDH mRNAs.
Plasmid rat IL-1RI 3'-clone containing a 3'-fragment (nt 473–1,826 of accession no. M95578) of the rat IL-1RI cDNA cloned into the Smal I site of pBluescript SK (Stratagene) was used. Linearization of this plasmid with Hind III and transcription with T3 RNA polymerase produced an ~520-nt-long antisense probe that protects 436 nt in the rat IL-1RI mRNA. Rat IL-1R AcP cDNA (nt 874–1,212 of accession no. U48592) cloned into Eco RV site of pBluescript SK was used. Linearization of this plasmid by Hind III and transcription by T3 RNA polymerase resulted in an ~420-nt-long antisense probe that protects 339 nt in the membrane-bound form of rat IL-1R AcP; additionally, this probe protects a shorter fragment corresponding to the soluble form of IL-1R AcP (5, 7).

Plasmid pBS-RA containing a fragment (nt 3–451 of accession no. M63101) of the rat IL-1Ra cDNA was linearized with Bsa I and transcribed with T3 RNA polymerase to produce an ~250-nt-long antisense probe that protects 207 nt in the rat IL-1Ra mRNA.

Plasmid pTRI-trans(T7) containing the peptide-coding portion of rat TNF-α cDNA (nt 1–708 of accession no. S40199) was used. Linearization of this plasmid by Eco RI and transcription with SP6 RNA polymerase produced an ~790-nt-long antisense probe that protects 708 nt in the rat TNF-α mRNA.

Rat TGF-β1 cDNA (accession no. X52498) cloned into pBluescript KS vector (Stratagene) was used. Linearization of this plasmid by BamHI and with T3 RNA polymerase produced an ~320-nt-long antisense probe that protects 244 nt in the rat TGF-β1 mRNA.

Rat POMC cDNA cloned between Bbs I and Eco RI sites of pBS vector was used. This cDNA was linearized with Bsa I and transcribed with T3 RNA polymerase to produce an ~590-nt-long antisense probe that protects 530 nt in the rat gp130 mRNA.

Rat gp130 cDNA (accession no. M92340) cloned into Eco RI site of pBS vector was used. This cDNA was linearized with Bsa I and transcribed with T3 RNA polymerase to produce an ~320-nt-long antisense probe that protects 244 nt in the rat TGF-β1 mRNA.

Rat gp130 cDNA cloned between BamHI and Eco RI sites of pBluescript KS(+) vector was used. The plasmid was linearized with Xmn I, and T3 RNA polymerase transcription resulted in an ~320-nt-long antisense probe that protects 264 nt in the rat POMC mRNA (predominant form).

Plasmid pBLNPY-1 containing a 511-bp insert (accession no. M20373) composing most of the cDNA of rat preproNPY ligated into the Eco RI I site of vector Bluescribe M13(-) was used. Linearization of the plasmid with Bbs I and transcription with T3 RNA polymerase produced an ~242-nt-long antisense probe that protects 180 nt in the rat NPY mRNA.

Rat antisense template pTRI-GAPDH (Ambion, which contains a 316-nt fragment of the rat GAPDH gene) was used to generate the GAPDH antisense probe. Antisense template pTRI-β-actin-125-Rat (Ambion, which contains a 126-bp cDNA fragment of the rat β-actin gene) was used to generate the β-actin antisense probe.

Data analyses. All results are expressed as means ± SE. Data were analyzed using ANOVA and, where appropriate (i.e., after a significant main effect), were followed by post hoc tests for pairwise comparisons (Student-Newman-Keuls method). A Kruskal-Wallis test was applied (followed by post hoc tests) when data did not pass the normality (Kolmogorov-Smirnov) and equal variance (Levene median) tests. Data were also analyzed using t-test or Mann-Whitney test (when data did not pass normality and equal variance tests). Differences were considered significant only for P < 0.05.

RESULTS

Food intake. The data are summarized in Fig. 1. Total daily food intake decreased gradually in the Lobund-Wistar rats bearing prostate adenocarcinoma tumor cells. The average total daily food intake was 19.2 g for days 11-19, 17.8 g for days 20-24, 16.0 g for days 25-32, and 13.3 g for the last 4 days (days 33-36). Each period was significantly different from each other period (Fig. 1). Data from days 1-10 are not available because of the rats' transit and quarantine procedures. However, during the initial 5 days of measurement (days 11-15), food intake was similar in both groups [mean of 19.8, 19.1, 20, 19.7, and 19.4 g for days 11-15, respectively, in tumor-bearing rats (n = 7) and 18.9, 18.6, 19.5, 19.5, and 18.9 g, respectively, in controls (n = 7)]. Thereafter, as required, the amount of food given to the control group was adjusted according to the amount of food eaten by the tumor-bearing rats during the previous day. Pair feeding continued until death. At the end of the behavioral monitoring period (36 days after tumor cell inoculation or vehicle administration), the body weights were 327 ± 11 g (n = 7) in the tumor-bearing Lobund-Wistar rats and 323 ± 4 g (n = 7) in the pair-fed controls. These data show that body weights were not significantly different. It should also be noted that animals were killed during the period of early moderate anorexia induced by the tumor; that is, rats were still eating >10 g of food. The subcutaneous tumors were noticeable but small. Thus food intake and body weight data indicate that none of the rats used in this study exhibited significant deterioration that is associated with severe long-term anorexia and the anorexia-cachexia syndrome.

RNase protection assay of IL-1β, IL-1Ra, IL-1RI, IL-1R AcP I and II, TNF-α, TGF-β1, gp130, POMC, NPY, β-actin, and GAPDH mRNAs. The levels of IL-1β system, TNF-α, TGF-β1, gp130, POMC, NPY, β-actin, and GAPDH mRNAs were determined in the cerebellum, parietofrontal cortex, and hypothalamus from Lobund-Wistar control and tumor-bearing rats. The same rats (n = 7 per group) were used to monitor the behavior and analyze the IL-1β system, TNF-α, TGF-β1, gp130, POMC, NPY, β-actin, and GAPDH mRNA levels in brain regions. Figures 2 and 3 present ex-
amples of the RNase protection assays used. As shown, samples from both control and tumor-bearing groups and the three brain regions were analyzed concomitantly. Consistency was verified by analyzing all samples individually, from which all means ± SE were generated. It should also be noted that each individual sample was obtained from a different rat, that the same rat provided all three brain regions, and that the same samples were analyzed with all of the antisense probes as described in MATERIALS AND METHODS. The levels of rat β-actin mRNA (Fig. 2) and GAPDH mRNA (Fig. 3) were relatively constant between treatments within a brain region; this indicates consistency of processing and that an equal amount of total cell RNA was used for each assay. Moreover, the specificity of the probes used has been demonstrated previously by various procedures (7, 21), including control experiments on hybridization specificity in which no signal corresponding to IL-1β, IL-1Ra, IL-1RI, IL-1R AcP, TNF-α, TGF-β1, gp130, POMC, or NPY mRNA was detected.

IL-1β mRNA in brain regions from control and tumor-bearing rats. The profile of IL-1β mRNA in the cerebellum, cortex, and hypothalamus is shown in Fig. 4.

ANOVA showed that groups differed significantly in IL-1β mRNA \( F(5, 36) = 23.0, P < 0.0001 \), power of performed test (ppt) = 1.0. All three brain regions examined had robustly significant differences between the control and tumor-bearing groups: cerebellum, \( P = 0.0008 \), ppt = 0.98; cortex, \( P < 0.0001 \), ppt = 1.0; and hypothalamus, \( P < 0.0005 \), ppt = 0.99.

IL-1Ra mRNA in brain regions from control and tumor-bearing rats. The data are summarized in Fig. 5. No significant difference in IL-1Ra mRNA levels between groups was observed in the cerebellum (\( P = 0.5 \)). The cortex, on the other hand, exhibited a significant increase in IL-1Ra mRNA levels in the tumor-bearing group relative to the control group (\( P < 0.0001 \), ppt = 1.0). The difference in the hypothalamus was also significant (\( P < 0.05 \)).
IL-1RI mRNA in brain regions from control and tumor-bearing rats. The profile of the IL-1 signaling receptor mRNA is summarized in Fig. 6. The difference in IL-1RI mRNA levels in the cerebellum was not significant (P = 0.1). On the other hand, IL-1RI mRNA levels were significantly increased in the cortex (P = 0.001) and hypothalamus (P = 0.0006) obtained from tumor-bearing rats.

IL-1β mRNA and IL-1Ra mRNA in the tumor. The prostate gland from control Lobund-Wistar rats had undetectable levels of IL-1β mRNA. On the other hand, the signal for IL-1β mRNA was robust in all tumor samples taken from the tumor-bearing rats (n = 7).

DISCUSSION

The data show that anorectic tumor-bearing Lobund-Wistar rats exhibit an upregulation of IL-1β mRNA in discrete brain regions (cerebellum, cortex, and hypothalamus). IL-1Ra mRNA and IL-1RI mRNA levels are also significantly increased in the cortex and hypothalamus. All other cytokine components, POMC, or NPY mRNA levels in the brain regions examined were observed.

TNF-α mRNA in brain regions from control and tumor-bearing rats. The data are summarized in Table 1. TNF-α mRNA levels were not significantly different in the three brain regions examined.

TGF-β1 mRNA in brain regions from control and tumor-bearing rats. The data are also summarized in Table 1. The levels of cerebellar, cortical, and hypothalamic TGF-β1 mRNA did not differ significantly between control and tumor-bearing rats.

gp130 mRNA, POMC mRNA, and NPY mRNA in brain regions from control and tumor-bearing rats. As shown in Table 2, no significant differences in gp130, POMC, or NPY mRNA levels in the brain regions examined were observed.

IL-1β mRNA and IL-1Ra mRNA in peripheral organs from control and tumor-bearing rats. We also examined IL-1β mRNA and IL-1Ra mRNA levels in two peripheral organs, the spleen and liver. Peripheral tissue samples were obtained from the same rats that provided the brain regions. The data obtained in the spleen are summarized in Fig. 7. Both IL-1β mRNA and IL-1Ra mRNA levels were significantly increased in the Lobund-Wistar rats bearing prostate adenocarcinoma tumor cells relative to the controls. The liver also exhibited significantly higher levels of IL-1Ra mRNA (32.6 ± 1.1 arbitrary units in tumor-bearing rats vs. 18.1 ± 2.2 arbitrary units in controls; t = 5.26, P = 0.0004, ppt = 1.0).

Values are means ± SE (standardized to arbitrary units) from 7 individual samples examined for each case. Tumor necrosis factor (TNF)α and transforming growth factor (TGF)β1 mRNAs were examined in same brain region samples used to determine all other mRNA components.
mRNA levels were not significantly different between tumor-bearing and control rats. These data suggest that IL-1β mRNA upregulation in the brain may be relevant to the early anorexia exhibited by the Lobund-Wistar rat bearing prostate adenocarcinoma tumor cells. Previous studies proposed that IL-1 can participate in the induction and progression of cachexia (4, 18, 31). Using a colon tumor model, Strassmann et al. (31) showed that intratumoral administration of IL-1Ra significantly reduced the cachexia associated with the tumor. Gelin et al. (4) also reported that treatment of rodents bearing methylcholanthrene-induced sarcoma with monoclonal antibodies against the IL-1R inhibited tumor growth and improved food intake. Moreover, the growth of Morris hepatoma in rodents was also associated with increased levels of IL-1 in the spleen (13).

The present study is the first to report upregulation of IL-1β mRNA in peripheral organs and discrete brain regions of the same rat responding to a peripheral tumor. The consistent increase in levels of IL-1β mRNA in the tumor, spleen, and discrete brain regions suggests that the tumor induces a series of events that result in local organ production of IL-1β. This is supported by our data because we used IL-1β mRNA as an index of local production of the cytokine. Thus the evidence suggests that local production of IL-1β in the brain (e.g., hypothalamus, an important feeding-regulatory brain site) could be involved in the induction of early anorexia or exacerbation of early anorexia in the Lobund-Wistar model of prostate cancer. This is consistent with the fact that IL-1β induces anorexia by direct action in the hypothalamus (18) and the report that intrahypothalamic administration of IL-1Ra improves feeding in anorectic rats bearing methylcholanthrene-induced sarcoma cells (11).

IL-1Ra mRNA and IL-1RI mRNA levels were also upregulated in brain regions. IL-1Ra mRNA upregulation accompanies IL-1β mRNA upregulation in various models (8, 21, 22). A balance between IL-1β and IL-1Ra appears critical for an appropriate modulation of IL-1β-associated cellular responses in the brain (8, 21). However, a significant excess of IL-1Ra is required to modulate IL-1β-induced cellular responses because the IL-1 system exhibits spare receptor effects, with maximal biological response observed with occupancy of only 1–10% of IL-1 receptors. We have discussed this modulation in detail (21). Upregulation of IL-1RI mRNA may also participate in the modulation of cellular responses to IL-1β (8, 21).

The brain region cytokine profile obtained in Lobund-Wistar rats bearing adenocarcinoma tumor cells is significantly different from the brain cytokine profile observed in all other rodent models we have investigated. In various models, for example, using specific bacterial products (22), viral glycoproteins (7), or cytokines (8, 21), TNF-α and TGF-β1 mRNAs are also significantly modulated. This indicates that distinct cytokine profiles and cytokine-cytokine interactions occur in brain regions depending on the underlying pathophysiological process or challenge.

Values are means ± SE (standardized to arbitrary units) from 7 individual samples examined for each case. Levels of proopiomelanocortin (POMC) in cerebellum and cortex were below sensitivity of detection. Glycoprotein 130 (gp130), POMC, and neuropeptide Y (NPY) mRNAs were examined in the same brain region samples used to determine all other mRNA components.

![Fig. 7: IL-1β mRNA and IL-1Ra mRNA levels in spleen from control and tumor-bearing rats. *P < 0.001 compared with controls.](http://ajpregu.physiology.org/)

The brain region cytokine profile obtained in Lobund-Wistar rats bearing adenocarcinoma tumor cells is significantly different from the brain cytokine profile observed in all other rodent models we have investigated. In various models, for example, using specific bacterial products (22), viral glycoproteins (7), or cytokines (8, 21), TNF-α and TGF-β1 mRNAs are also significantly modulated. This indicates that distinct cytokine profiles and cytokine-cytokine interactions occur in brain regions depending on the underlying pathophysiological process or challenge.
Our previous studies also showed that cytokine-cytokine (29) and cytokine-neuropeptide (30) interactions are important in cytokine-induced anorexia, depending on the model. The present study examined other components associated with feeding: gp130, POMC, and NPY mRNAs. These did not differ significantly in any brain region between control and tumor-bearing rats. This suggests that early anorexia in the Lobund-Wistar rat model of prostate cancer is not associated with changes in hypothalamic mRNA for gp130 [a transducer among receptors for IL-6 subfamily receptors members that have been shown to induce anorexia (19)]. POMC (opioid peptide precursor that generates various feeding-modulatory opioid peptides), or NPY (a feeding-enhancer peptide proposed to participate in the maintenance of normal feeding). A previous study reported that hypothalamic concentration and release of NPY was reduced in anorectic rats bearing methylcholanthrene-induced sarcoma (2). Thus tumor type and clinical stage of the malignant process could be associated with differential neuropeptide profiles.

Perspectives

The data show that in vivo characterization of cytokine components in discrete brain regions during cancer induction and progression is essential to understand the underlying molecular mechanisms [including cytokine-neurotransmitter-neuropeptide interactions (20)] responsible for cancer-associated neurological manifestations. For example, cytokine upregulation in the hypothalamus is relevant to cancer anorexia, whereas in the cerebral cortex it could be involved in the induction of neuropsychiatric manifestations (e.g., depression, anxiety, and delirium) that commonly occur during cancer. Cytokine profile characterization in other organs may also be relevant to the understanding of the mechanisms involved in the host's biochemical and physiological response to tumor progression.

We thank Dr. Morris Pollard (Lobund Laboratory, University of Notre Dame) for providing the Lobund-Wistar rats. We also thank Dr. Ronald P. Hart (Department of Biological Sciences, Rutgers University) for providing the rat IL-1β, IL-1Ra, IL-1RI, and IL-1R1 ACP cDNAs; Dr. Karl Decker (Biochemisches Institut der Albert Ludwigs Universität) for providing the rat TNF-α cDNA; Dr. David Danielpour (National Cancer Institute) for providing the rat TGF-β1 cDNA; Dr. Gerald M. Fuller (Department of Cell Biology and Anatomy, University of Alabama at Birmingham) for providing the rat gp130 cDNA; Dr. Andrea Gore (Center for Neurobiology, The Mount Sinai Medical Center) for providing the rat POMC cDNA; and Dr. Steven L. Sabol (Laboratory of Biochemical Genetics, National Heart, Lung, and Blood Institute) for providing the rat NPY cDNA.

Received 5 February 1998; accepted in final form 8 May 1998.
