Submitted 13 August 2015; accepted in final form 31 March 2016

A MAJOR EPIDEMIC of chronic kidney disease is occurring in Central America among workers in the sugarcane fields. To date there have been reported to be over 20,000 deaths. While the etiology is unknown, most studies suggest that recurrent dehydration with soft drink-like beverages exacerbates dehydration and worsens dehydration-associated renal injury. Am J Physiol Regul Integr Comp Physiol 311: R57–R65, 2016. First published April 6, 2016; doi:10.1152/ajpregu.00354.2015.—Recurrent dehydration, such as commonly occurs with manual labor in tropical environments, has been recently shown to result in chronic kidney injury, likely through the effects of hyperosmolarity to activate both vasopressin and aldose reductase-fructokinase pathways. The observation that the latter pathway can be directly engaged by simple sugars (glucose and fructose) leads to the hypothesis that soft drinks (which contain these sugars) might worsen rather than benefit dehydration associated kidney disease. Recurrent dehydration was induced in rats by exposure to heat (36°C) for 1 h/24 h followed by access for 2 h to plain water (W), a 11% fructose-glucose solution (FG, same composition as typical soft drinks), or water sweetened with noncaloric stevia (ST). After 4 wk plasma and urine samples were collected, and kidneys were examined for oxidative stress, inflammation, and injury. Recurrent heat-induced dehydration with ad libitum water repletion resulted in plasma and urinary hyperosmolarity with stimulation of the vasopressin (copeptin) levels and resulted in mild tubular injury and renal oxidative stress. Rehydration with 11% FG solution, despite larger total fluid intake, resulted in greater dehydration (higher osmolarity and copeptin levels) and worse renal injury, with activation of aldose reductase-fructokinase, whereas rehydration with stevia water had opposite effects. In animals that are dehydrated, rehydration acutely with soft drinks worsens dehydration and exacerbates dehydration associated renal damage. These studies emphasize the danger of drinking soft drink-like beverages as an attempt to rehydrate following dehydration.

METHODS

Ethical Approval

This investigation was performed in accordance with the “Guide for the Care and Use of Laboratory Animals” published by the National Institutes of Health, and the Mexican Federal Regulation for animal experimentation and care (NOM-062-ZOO-2001) and for the disposal of biological residues (NOM-087-ECOL-1995).

Reagents

Chemicals were of reagent or higher grade from Sigma-Aldrich (St. Louis, MO) unless otherwise specified. Antinmurytin neutral phel gelatinase-associated lipocalin (N-GAL), antinephrin, antivasopressin V1a receptor, anti-superoxide dismutase (SOD)-1, anticatalase, and anti-GPx anti-antibodies were purchased from Santa Cruz Biotech-
ology (Dallas, TX). Antifructokinase (KHK) and aldose reductase were obtained from GenTex (Irvine, CA), antivasopressin V2 receptor antibody was obtained from Abcam (Cambridge, MA), and anti-β-actin antibody was obtained from Cell Signaling (Danvers, MA). Secondary antibodies conjugated with horseradish peroxidase were from Cell Signaling.

Experimental Protocol

Heat-induced dehydration protocol. Three groups of male Wistar rats were placed in a 36°C closed environment for 1 h without food and water from Monday to Friday during 4 wk. Thermal exposure is considered a valid model to induce dehydration in rats (2–6, 29–31). After heat-induced dehydration, animals were allowed to rehydrate for 2 h with either tap water (W, n = 6), a sweetened beverage made with an 11% of a fructose-glucose combination, which is a similar composition used in major brands of soft drinks (FG, 7.15% fructose and 3.85% glucose, respectively, n = 7) (10, 12), or water sweetened with the noncaloric edulcorant stevia (ST) (4 g/l water, Svetia, Metco Mexico, n = 7). Pelleted food was provided ad libitum. For the rest of the day and during weekends animals received tap water and food ad libitum. The loss of weight induced by heat and the amount of drinking fluid consumed during rehydration period were recorded daily.

Normal control group (C). This group consisted of five male Wistar rats of similar body weight and age. They received food and water ad libitum during 4 wk. The amount of water and food consumed were measured daily. Body weight was measured weekly.

Measurements

At the end of the 4-wk study period, systolic blood pressure was measured, and urine was collected for 18 h (overnight) in metabolic cages. Food was not provided during the urine collection. Rats were then euthanized by anesthesia with isoflurane and exsanguination. A blood sample was collected and centrifuged. Plasma and urine samples were frozen until further analyses. Both kidneys were perfusion washed with cold phosphate-buffered saline, and the right kidney was excised and divided into cortex and medulla, frozen in liquid nitrogen, and stored until further processing. The left kidney was fixed by perfusion with 4% paraformaldehyde for histology.

Blood and Urine Analyses

Plasma and urine osmolality was measured using a freezing point depression osmometer (Advanced Instruments, Norwood, MA). Plasma and urine creatinine were measured by a validated enzymatic method (22) and creatinine clearance was calculated. Plasma and urine urea nitrogen concentrations were analyzed by autoanalyzer (Instrumentation Laboratory, Bedford, MA). Sodium concentration was analyzed by flame photometry. Fructose was measured by a colorimetric assay (18), and uric acid was measured with a fluorometric kit (Amplex Red, Life Technologies, Carlsbad, CA). Plasma copeptin was extracted using Sep-pack C18 cartridges (Waters, Milford, MA) and then measured by a rat-specific competitive enzyme immunoassay (Peninsula Laboratories, San Carlos, CA).

Solute-free water reabsorption (TfH2O) during the 18 h of urine collection was calculated according to the following formula: TfH2O = osmolar excretion − urine volume = (Uosm/Posm) × V − V, where Uosm and Posm are the urine and plasma osmolality, respectively, and V the urine volume collected in 18 h.

Blood Pressure

Systolic blood pressure (SBP) was measured in conscious rats by a validated volume-based tail-cuff method (17) at the end of the follow-up.

Evaluation of Markers of Tubular Damage

For the determination of N-acetyl-β-D-glucosaminidase (NAG) activity in urine samples, 4-nitrophenyl-N-acetyl-β-D-glucosaminide was used as a substrate. Neutrophil gelatinase-associated lipocalin (NGAL) expression, a sensitive marker of renal proximal tubule damage (25), was evaluated by Western blotting. Renal cortex proteins were extracted using a mitogen-activated protein (MAP) kinase lysis buffer, as previously described (33), and incubated with a primary antibody against NGAL (Santa Cruz Biotechnology) at 4°C overnight, using β-actin antibody (Cell Signaling) as load control.

Renal Cortex Content of Fructose and Uric Acid

Fructose was extracted from cortical renal tissue by perchloric acid precipitation, and its concentration was measured by the anthrone-based colorimetric method (18). Uric acid (UA) is a byproduct of fructose catabolism in tissues expressing KHK and is associated with its detrimental effects (21). Therefore, tissue UA was measured both as a marker of renal damage and also as a surrogate of fructose increased metabolism. UA was extracted as previously described (11). UA was measured using Amplex Red assay kit (Life Technologies). Fructose and UA concentrations were normalized by protein concentration.

Renal Cortex Markers of Oxidative Stress

Tissue was homogenized in phosphate buffer containing a cocktail of protease inhibitors. Protein carbonyl and lipid peroxidation (4-hydroxynonenal, 4-HNE) were measured using previously published methods (27, 39) and normalized by protein concentration. NOX4, catalase, glutathione peroxidase, and superoxide dismutase-I protein expression. Renal cortex proteins were extracted using a MAP kinase lysis buffer, as previously described (22). Each of the following primary antibodies were incubated at 4°C overnight: anti-NOX4 (GeneTex, Irvine, CA), anticalcatase, -GPx, and anti-SOD-1. Protein loading was controlled with anti-β-actin antibody (Cell Signaling). Chemiluminescence was captured using Clarity horseradish peroxidase chemiluminescence kit (Bio-Rad, Hercules, CA) and exposure of membranes over X-ray film inside a standard developing cassette. Film was developed manually and exposure was repeated varying the time as needed for optimal detection; thereafter the film was scanned. Blots were recorded, and densitometry was performed using the Image Studio Lite Software (Licol, Lincoln, NE).

Aldose reductase, KHK, and vasopressin V1a and V2 receptors protein expression by Western blot analysis. Renal cortex proteins were extracted using a MAP kinase lysis buffer, as previously described (33). Each of the following primary antibodies were incubated at 4°C overnight: anti-KHK (GeneTex, Irvine, CA), anticalcatase, V1a receptor (Santa Cruz Biotechnology), antivasopressin V2 receptor (Abcam), and anti-β-actin antibody (Cell Signaling). Chemiluminescence was recorded and quantified using the Image Studio Lite Software (Biotech, Lincoln, NE).

Histological Analysis

Fixed renal tissue was embedded in paraffin and processed accordingly. The evaluation was performed blinded. Sections were stained with periodic acid–Shiff’s stain (PAS). Glomerular changes (glomerulosclerosis or hypoperfusion as evidenced by wrinkling and collapse of the glomeruli) were qualitatively evaluated. Tubulointerstitial cellular infiltration was studied in PAS-stained sections taking advantage that the nucleus of inflammatory cells is stained in dark blue. The number of inflammatory cells were quantified in 20 nonoverlapping fields at ×400 magnification and expressed as positive cells in 20 fields.

SUGARY BEVERAGES WORSEN DEHYDRATION-INDUCED RENAL INJURY

Statistical Analysis

Values are expressed as means ± SD. One-way ANOVA determined significant differences between groups. When the ANOVA P value was <0.05, posttest comparisons were made using Sidak’s multiple-comparison test assuming an α/df (per family of tests) = 0.05. Each computed P value was adjusted to account for six multiple comparisons per family. The possible relationship between variables was tested by correlation analysis. Statistical analysis was performed with Prism version 6.05 (Graph Pad Software, San Diego, CA).

RESULTS

Dehydration Protocol

The central hypothesis of this study was that rehydration with fructose/glucose concentrations similar to that observed in soft drinks might accelerate heat-induced dehydration renal injury. Heat-induced dehydration was performed by exposure of rats daily to heat (1 h at 36°C) followed by 2 h of ad libitum rehydration with either water of a fructose-glucose (FG) solution similar in composition to that present in soft drinks. The rest of the 24-h period all groups only received water for fluid intake. Because rats drank more FG solution than regular water, we also included a group given stevia water, as rats drank the same amount of stevia water as FG water thus providing a control for fluid intake following the dehydration procedure. These three groups were then compared with normal control rats that were not exposed to heat.

Effects on Weight and Fluid Intake

Heat-induced dehydration resulted in equivalent mean daily body weight loss among the three groups (water, stevia, and FG) at the end of the heat period (Table 1). During the 2-h ad libitum rehydration period, rats administered FG and stevia water drank more fluid (~30%) compared with water alone. However, total 24-h water intake was similar among the three groups (Table 1), although it was higher than the normal control group.

Rehydration With Soft Drinks is Associated With Evidence for Persistent Dehydration Despite Normal Renal Function

Rats underwent blood testing in the morning after having ample time to be rehydrated. Despite daily rehydration, rats that had been exposed to daily heat showed higher mean levels of plasma and urine osmolarity with higher plasma copeptin levels compared with normal control rats (Fig. 1). Nevertheless, rats hydrated with FG showed significantly higher plasma and urine osmolarity and higher copeptin levels and higher free water reabsorption by the kidneys despite greater fluid intake during the 2-h rehydration period (Fig. 1). In contrast, rehydration with stevia water was associated with lower plasma osmolarity and lower copeptin levels than that observed with water alone.

Heat-induced dehydration raised absolute sodium urine excretion and sodium fractional excretion; this effect was enhanced in FG-rehydrated group. In contrast, in rats rehydrated with stevia the rise in sodium excretion, both absolute and fractional, was prevented (Table 1).

Heat-induced dehydration alone also increased blood pressure compared with normal control rats. Rehydration with FG did not further raise blood pressure. Stevia rehydration was associated with lower blood pressure than the group rehydrated with water (Table 1).

In summary, recurrent and transient heat-induced dehydration results in some persistent evidence for dehydration (elevations in plasma and urine osmolarity, elevated copeptin levels) and this is significantly worse in rats rehydrated with FG solutions.

Renal Injury Induced by Dehydration is Worsened by Rehydration With Soft Drink

No differences in plasma urea were observed in these four groups as measured in the fasting morning blood samples. However, rehydration with FG solutions to heat-exposed rats...
significantly increased plasma creatinine and decreased Cr clearance (Table 1).

We evaluated two markers of proximal tubule damage: NAG urine excretion and the expression of NGAL. In rats that received FG as rehydration fluid there were significant increments in the excretion of NAG in urine and in NGAL renal cortex expression. Rehydration with stevia prevented those changes (Fig. 2A).

We also evaluated whether renal structural damage was already present. Dehydrated rats with FG rehydration had significantly more glomerular hypoperfusion and glomerulosclerosis compared with water and stevia rehydration (Fig. 2B). Mild tubulointerstitial inflammation was also observed in the group that received FG.

These data document that heat-induced dehydration is associated with both structural and urinary biomarker evidence of renal injury and this is worsened with hydration using FG solutions.

**Potential Mechanisms for Renal Injury: Aldose Reductase-Fructokinase-Uric Acid Pathway and the Vasopressin Pathways**

We also measured uric acid and fructose as both may be induced by dehydration [by renal retention of uric acid coupled with increased generation of both fructose and uric acid via the aldose reductase pathway (34)]. As expected, heat-induced dehydration was associated with a numerical rise in plasma uric acid and a significant rise in urine fructose, although no change in plasma fructose from normal controls was observed (Table 1). In contrast, rehydration with FG was associated with similar rise in plasma uric acid as control heat-dehydrated rats, but with higher plasma levels, despite that urine levels were found similar to water rehydrated rats. Stevia-treated rats showed lower plasma uric acid and comparable levels of plasma and urine fructose as control rats.

In renal cortex of rats that received water as rehydration fluid, concentrations of fructose and uric acid were not different compared with normal control rats (Fig. 3). On the contrary, rats that received FG during rehydration period, a significant increment in the concentration of fructose and uric acid were observed. In stevia-rehydrated groups, fructose and uric acid renal concentrations remained comparable to water rehydrated and control groups (Fig. 3).

As activation of fructokinase-uric acid pathway is associated with increased oxidative stress via activation of NOX4 (23, 35, 37, 44), we also evaluated lipid peroxidation and protein oxidation in renal cortex (Fig. 3). Heat-dehydrated rats that received water as rehydration fluid showed a slight but significant increment in lipid peroxidation and protein oxidation in renal cortex (Fig. 3). The increased content of fructose and uric acid induced by rehydration with FG was associated with a significant augmentation in oxidative stress as noted by a further increase in lipid peroxidation and protein oxidation. Stevia rehydration was associated with lower oxidative stress compared with FG groups. In agreement with the increment in oxidative stress observed in dehydrated rats rehydrated with FG beverage, we also observed significant overexpression of NOX4 as well as the antioxidant enzymes catalase, glutathione peroxidase (GPx), and SOD-1 in the kidneys (Fig. 3).

We also evaluated the renal cortex expression of the enzymes involved in fructose-uric acid pathway and vasopressin receptors (Fig. 4). Rats that the received water as rehydration fluid showed a slight but significant increment in the expression of aldose reductase in renal cortex. In parallel to the further increment in cortex fructose, uric acid and oxidative stress, the group of dehydrated animals that received FG for rehydration showed a significant increment in the expression of fructokinase, vasopressin receptors 1a and 2, and a further increase in the expression of aldose reductase. In contrast, rats that received stevia did not showed those changes (Fig. 4).
DISCUSSION

In this study, we tested the hypothesis that the type of rehydration solution might influence renal outcomes associated with recurrent mild dehydration. Specifically, we hypothesized that short-term rehydration with sugary beverages containing fructose might have adverse effects on the kidney. To test this hypothesis, we performed studies in a model of thermal dehydration and compared water, stevia-containing water, and a solution of fructose-glucose that is similar in composition to standard soft drinks. The present study shows that short-term rehydration with a FG sugary beverage after a mild dehydration stimulates the two systems that have been implicated in kidney injury, i.e., vasopressin (1) and aldose reductase-fructokinase activities (34). After rehydration with a fructose-rich beverage, we observed a greater renal oxidative stress and mild renal injury (glomerular and tubular alterations). In contrast, rehydration with plain water or with the noncaloric edulcorant stevia did not produce such deleterious effects.

Fructose is a substrate for fructokinase that is present in the proximal tubule, and a 60% fructose diet in rats can induce modest tubular injury (11, 28). Fructose infusion in humans

AJP-Regul Integr Comp Physiol • doi:10.1152/ajpregu.00354.2015 • www.ajpregu.org

Fig. 2. Markers of tubular injury in mildly dehydrated animals (A) and glomerular changes (B) evaluated as percentage of glomeruli affected by hypoperfusion and glomerulosclerosis as well as tubulointerstitial inflammation (Peryodic acid Schiff’s staining, ×400 magnification) in the various studied groups. Statistical comparisons: A vs. normal control; B vs. water C vs. FG.
can also stimulate vasopressin release, whereas an equimolar solution of glucose does not (42). Our basic hypothesis was that recurrent stimulation of these pathways might induce renal disease and that hydration with fructose-containing solutions could increase vasopressin release and provide a substrate for fructokinase that might lead to further renal damage.

The type of rehydration fluid had significant effects on most of the outcomes. The administration of FG but not that of ST as rehydration fluid resulted in a further and significant increment in plasma copeptin. Moreover, rats continued to show signs of dehydration with higher urine osmolality and increased free water reabsorption, likely due in part to increased urinary sodium excretion observed in the FG-rehydrated rats. The evidence for worse dehydration despite increased fluid intake compared with the water-only group was striking. The consequence was also a greater renal oxidative stress, renal tubule injury, and subtle inflammatory infiltration. An additional marker of renal impairment in fructose-rehydrated rats was a significant fall in creatinine clearance. This finding suggests that glomerular filtration was reduced in this condition. However, it cannot be excluded that the observed differences in the creatinine clearances are due to different renal handling of creatinine by organic anion and/or cation transporters (16, 40).
An effect of a beverage containing simple sugars as replacement fluid was a significant increase in the accumulation of fructose and uric acid in the renal cortex. In previous studies, we and others have reported that tissue accumulation of uric acid is associated with augmented oxidative stress and damage (12, 26, 35). The results of the present studies are in agreement with those previous works.

Dehydration tended to increase systemic blood pressure in W and FG- but not in ST-rehydrated rats. This effect may be a consequence of increased renal oxidative stress in those groups (41). Whether this adverse influence of the rehydration fluid on SBP participated in kidney damage deserves further investigation.

We have previously shown that recurrent exposure to heat can induce renal injury through a fructokinase-dependent mechanism. In that study, the dehydration procedure was severe (34). We have also shown that a 60% fructose diet induces renal damage in the course of 8 wk (36). Moreover, rats that received a similar FG beverage ad libitum developed mild renal damage; however, those animals ingested ~80 ml of this fluid per day (39) in contrast to the present study in which rats had a limited consumption of this sweetened beverage (12 ml/day). It was also observed that rats that received a similar daily amount of fructose/glucose beverage (14 ml/day) but without dehydration did not develop renal alterations (data not shown). Therefore, the power of the current study is that the renal injury was found even with very mild recurrent dehydration when short-term rehydration with fructose-containing beverages was provided.

An interesting finding in this study was that dehydration was associated with increased urinary sodium excretion and that this was worsened by the rehydration with FG. Although volume contraction is known to cause a prerenal state with a decrease in fractional excretion of sodium, dehydration-induced hyperosmolarity can cause a mild natriuresis (known as dehydration natriuresis) (13). The signaling mechanisms (Sgk1 and TonEBP) involved in causing dehydration-induced natriuresis are the same as those known to stimulate the aldose reductase-fructokinase pathway and thus may account for the potentiation of this mechanism with the FG solutions (13, 43). It was also observed a significant increase in urinary urea excretion in FG-rehydrated animals. We do not have a definite explanation for this effect; however, a mechanism that might contribute to increased urea excretion could be an overall increase in proteolytic activity induced by dehydration (9). Thus cellular dehydration is believed to be a driving force

Fig. 4. Renal cortex aldose-reductase, fructokinase (KHK), vasopressin V1a and V2 receptors expressions in mildly dehydrated animals induced by heat exposure in animals rehydrated for 2 h with water (W), an 11% fructose-glucose beverage (FG), and water sweetened with the noncaloric edulcorant stevia (ST). Statistical comparisons: A vs. normal control; B vs. water; C vs. FG.
behind the severe protein wasting observed within the liver and skeletal muscles of extremely ill patients (19).

There is evidence that water intake is decreasing in the general population (20). Taking into account that, at present, a common practice is to rehydrate with sugary beverages when the threshold of mild dehydration has been reached (a situation in which vasopressin secretion is already increased), these findings might provide evidence for a pathophysiological mechanism that partially explain the association between sugary beverages consumption and renal damage (7, 14, 38).

Finally, stevia solution used as rehydration fluid prevented the rise in vasopressin secretion and preserved plasma and urine osmolality to normal levels. In addition, stevia-rehydrated animals had normal blood pressure and no evidence of renal tubule damage. It is not possible to know if this protective effect is due to a significantly higher volume ingested for rehydration in the stevia groups than in the plain water groups or if it is an effect induced by stevia itself.

In conclusion, this study shows that short-term rehydration with fructose-containing beverages in rats undergoing mild recurrent dehydration results in enhanced renal injury in association with greater stimulation of the vasopressin and polyol-fructokinase pathways. The simultaneous triggering of both systems was associated with increased urinary concentration, oxidative stress, renal injury, and systemic hypertension. On the other hand, increased ingestion of fluids devoid of simple sugars (plain water or stevia solution) prevented the stimulation of vasopressin induced by mild dehydration.

**Perspectives and Significance**

This study is relevant to the epidemic of chronic kidney disease (CKD) in Central America, in which sugarcane and other workers are developing CKDs associated with recurrent heat-associated dehydration. However, it may also be an important factor in the high frequency of CKD that is occurring in hot climates such as Mexico and the southern United States. Further studies investigating the mechanisms involved in this injurious process are warranted in the future.

**GRANTS**

This study was funded by CONACyT Mexico No 133232 and No 155604, and INC Ignacio Chavez own funds allocated for research. R. J. Johnson also has funding from Amway and is on the Scientific Board of Amway. L.-G. Sánchez-Lozada, R. J. Johnson, and M. A. Lanasa have grants from Danone, National Institutes of Health, and the Department of Defense. Parts of the results of this paper were presented at the ASN Renal Week 2014, Philadelphia, PA. This paper represents a contribution from the Colorado Climate and Health Consortium.

**DISCUSSIONS**

R. J. Johnson and M. A. Lanasa are listed as inventors on patent applications related to blocking fructose metabolism as a means to prevent acute and chronic kidney disease. R. J. Johnson, C. Roncal-Jiménez and L.-G. Sánchez-Lozada are members of Colorado Research Partners. F. E. García-Arroyo, M. Cristóbal, A. S. Arellano-Bueno, H. Osorio, E. Tapia, V. Soto, L. Bankir, and M. Madero have no conflicts of interest to declare.
